Abstract. This report is an electronic appendix to our paper “The weak-heap family of priority queues in theory and praxis” presented at the 18th Computing: Australasian Theory Symposium that was held in Melbourne in January-February 2012. This report together with an accompanying `tar` ball gives the source code used in the experiments reported in that paper.

We implemented weak heaps and their close relatives weak queues as component frameworks that utilize the same collection of registries. By varying the registries used, our frameworks provide implementations for six different data structures: weak heap, weak queue, rank-relaxed weak heap, rank-relaxed weak queue, run-relaxed weak heap, and run-relaxed weak queue. Frameworks made policy-based benchmarking possible. We carried out extensive benchmarking with Dijkstra’s algorithm to compute shortest-path distances, and some syntactic data sets exploring the performance of these data structures in a worst-case scenario.

In its standard form a weak heap is implemented using an array. For a weak heap of size n , *insert*, *decrease*, and *delete-min* operations all take $O(\lg n)$ time in the worst case. By relying on a pointer-based implementation and by allowing a logarithmic number of nodes to break weak-heap ordering, *insert* and *decrease* operations can be supported in $O(1)$ worst-case time. For any sequence of *insert*, *decrease*, and *delete-min* operations, the bound obtainable for the number of element comparisons performed by a rank-relaxed weak heap is the best for all known priority queues; the bound is even better than that known for a Fibonacci heap.

In our experiments, for random data sets, non-relaxed versions performed best and rank-relaxed versions were slightly faster than run-relaxed versions. Compared to weak-heap variants, the corresponding weak-queue variants were slightly better in time but not in the number of element comparisons. For worst-case data sets, non-relaxed versions were slow for *decrease* and weak-queue variants were slightly faster than weak-heap variants. For *insert*, the logarithmic worst-case was hardly visible for weak heaps, whereas for relaxed versions the overhead caused by complicated transformations was clearly visible. For *delete-min*, all six data structures performed well. As a conclusion, we had to admit that the progress made by us was mainly analytical.

Keywords. Priority queues, shortest paths, weak heaps, weak queues, relaxed weak heaps, relaxed weak queues.

STL interface

§ 1 *meldable-priority-queue.h++*

```

1  /*
2  A meldable priority queue is a container which provides forward
3  iterators to the elements stored.
4
5  CPH STL guarantees:
6
7  1) Member function push() returns an iterator (or a handle) to the
8  given element and this iterator remains valid the whole life time of
9  the element.
10
11 2) Iterator operations take logarithmic time in the worst case.
12
13 3) Member function top() is a constant-time operation.
14
15 4) Member functions push(), pop(), erase(), and increase() have the
16 logarithmic worst-case cost.
17
18 5) Member function meld() is relatively fast having a
19 polylogarithmic worst-case cost.
20
21 6) The data structure uses a linear number of words in addition to
22 the elements stored.
23
24 Container requirements not fulfilled [C++ standard §23]:
25
26 7) For an iterator p, expressions --p and p-- are not supported.
27
28 8) For two meldable priority queues a and b, the following expressions
29 are not supported: a == b, a != b, a < b, a > b, a <= b, and a >= b.

§ 3 *priority-queue-iterator.h++*

```

1  /*
2   An iterator to be used in our priority-queue framework. Each
3   priority queue is a queue of perfect components. An iterator holds a
4   pointer to a node. To access the next node, we call the successor
5   for the given node; if the node has no successor in its current
6   component, the first node (if any) in the following component is
7   returned.
8
9   Observe that for meldable structures only unidirectional iterators
10  can be supported! Therefore, operator-- is not provided.
11

§ 9 lazy-mark-registry.h++

```

1  /*
2  A lazy mark registry keeps track of the marked nodes in a
3  run-relaxed heap. This registry is a duplicate registry with the
4  following characteristics:
5
6  – key: rank stored or deduced from the information stored at the nodes
7  – duplicate linking: maintain references to the marked nodes in a
8  small contiguous segment of memory called an arena; the nodes
9  themselves store an index to this arena, each occupying  $O(\lg n)$ 
10 bits (which can be held in a byte)
11 – access: a marked node of the given rank; marked nodes of type I and II
12 – duplicate reduction: divide the marked nodes into two categories:
13
14 I: A marked node belongs to this category if its parent is also
15 marked. If such a marked node exists, the number of marked nodes
16 can be reduced by applying the zig-zag and parent transformations,
17 or the parent, cleaning, and sibling transformations. However, a
18 marked node of the smallest rank of this type must be selected to
19 make the reduction possible (grandparent must be non-marked).
20
21 II: A marked node belongs to this category if its parent is
22 non-marked. If two such marked nodes exist, the number of marked
23 nodes can be reduced by applying the cleaning, pair, and parent
24 transformations.

§ 11 *root-registry.hpp*

```

1  /*
2  2  A root registry keeps track of the roots of the perfect weak heaps
3  3  in a weak queue. The interface is almost identical to that of a
4  4  level registry. In this particular implementation the regular
5  5  numeral system is used to maintain the sequence of digits denoting
6  6  the cardinality of heaps of some particular rank. This registry is
7  7  a duplicate registry with the following characteristics:
8  8
9  9  – key: rank stored at the nodes or computed on the fly
10 10 – duplicate linking: none since there are at most two duplicates per key
11 11 – access: a root of the given rank; the smallest rank having duplicates
12 12 – duplicate reduction: obey the rules of the numeral system
13 13
14 14 The digit sequence must be kept in the form (0 | 1 | 01*2)*.

§ 20 *pointer-based.weak-heap.h++*

```

1  /*
2  A pointer-based weak heap
3
4  A level registry has properties depth (get/set), root (get), and
5  leaf (get), and it has the member functions default constructor,
6  destructor, insert, extract, swap, show, is_valid.
7
8  A mark registry has the properties empty (get) and top (get),
9  and it has the member functions default constructor, destructor,
10 --first--, --next--, insert, extract, reduce, swap, show, is_valid.
11
